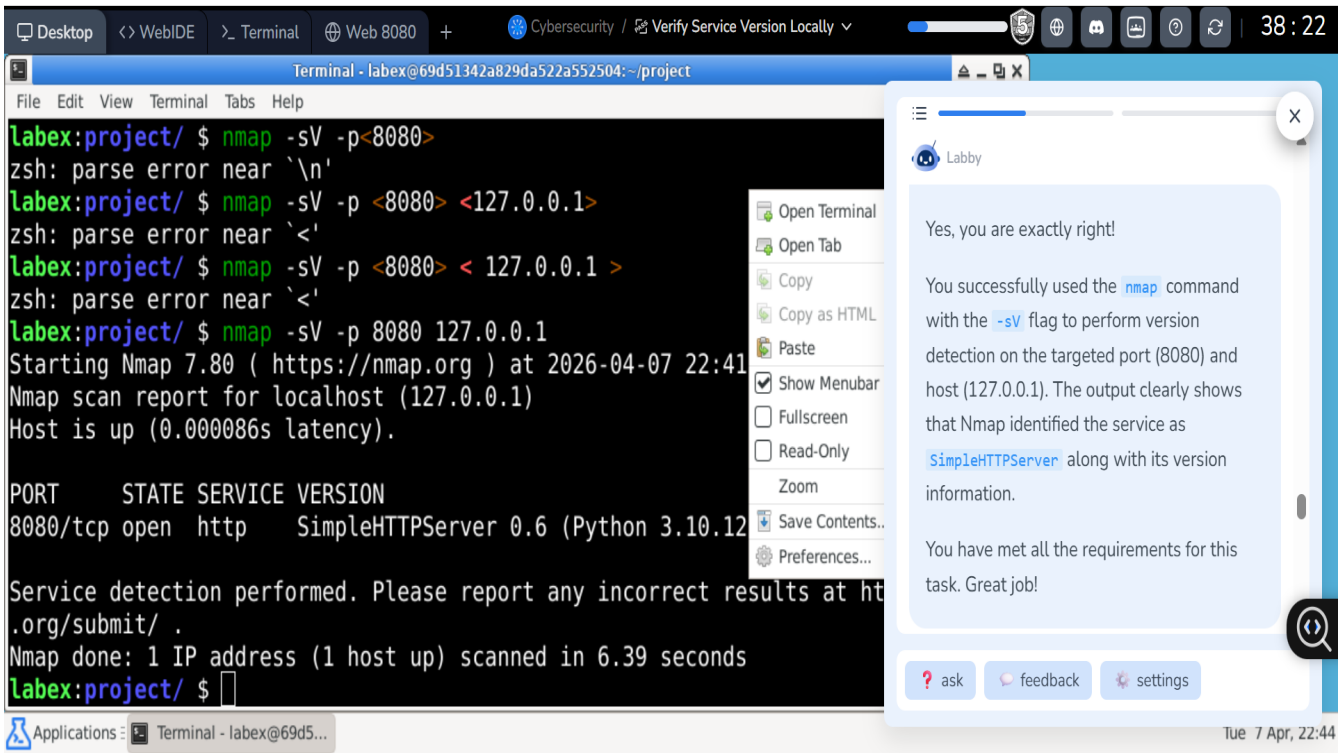
Nmap Project 2 – Professional Security Report



1. Objective

To identify the service and version running on a local machine using Nmap, simulating a real-world reconnaissance phase in cybersecurity.

2. Tools Used

• Nmap • Python HTTP Server • Linux Command Line

3. Methodology

A local web server was started on port 8080. Nmap was used with version detection to probe the service and extract banner information.

4. Command Executed

nmap -sV -p 8080 127.0.0.1

5. Findings

• Port 8080 is OPEN • Service: HTTP • Version: SimpleHTTPServer 0.6 (Python 3.10.12)

6. Analysis

The identified service version can be used to search for known vulnerabilities (CVEs), forming the basis for further security assessment.

7. Skills Demonstrated

• Network reconnaissance • Service enumeration • Nmap usage • Debugging command syntax

8. Conclusion

This project demonstrates a foundational penetration testing technique used to identify services and potential vulnerabilities in a system.
